

ABSTRACT OF THE DISCLOSURE

A drive control circuit executes a cycle at least once while a first movable part moves one pitch of an electrode of a plurality of groups of electrodes, the
5 cycle including a first operation for attracting the first movable part to a driving electrode substrate, a second operation for attracting the first movable part and a second movable part to stripe electrodes, a third operation for attracting the second movable part to the
10 driving electrode substrate, and a fourth operation for attracting the first and second movable parts to the stripe electrodes.
